meticulously organized by the College of Engineering/Warith Al-Anbiyaa University (CEWAU) and the distinguished Iraqi Scientific Geotechnical Society (ISGS) in in close collaboration with the world-renowned Peter the Great St. Petersburg Polytechnic University (SPbPU). ICGE-Iraq 2024 and WICES-2024 have a primary mission to serve as a formidable scientific platform, facilitating the presentation and in-depth discussion of the most recent and groundbreaking research and studies within the realm of geotechnical engineering. Furthermore, these conferences encompass a diverse array of related subjects spanning across civil engineering, environmental engineering, and architectural engineering. The conference presents a unique opportunity for both academic and industry professionals to engage in dynamic dialogues, exchange the most recent advancements in their respective fields, and forge invaluable connections. Participants will be able to share innovative insights, establish valuable business and research alliances, and identify prospective global partners for future collaborative endeavors. One of the notable objectives of these conferences is to construct a robust scientific communication bridge, connecting researchers in Iraq and Russia in the field of engineering sciences. This bridge is designed to facilitate the exchange of ideas, experiences, and expertise, promoting collaboration and knowledge sharing on an international scale.

Abstract

Normal text | **B** | *I* |  $X^1$  |  $X_1$  | | | |

Composite foundations are widely employed in transportation application such as roadways, highways, railways, and high-speed railways due to their cost-effectiveness and ability in reducing lateral displacement and settlement concerns. These foundations comprise several elements, including embankments, load transfer platforms, reinforced sections, and piles. The load transfer platform's significance lies in its ability to direct additional loads towards the piles, thereby reducing embankment settlement. To better understanding the load transfer mechanisms within composite foundations and the impact of geosynthetics on these foundations, a comprehensive study including a review of experimental and field tests and numerical analysis was presented in this study. The study also provides a summary of previous research findings and addresses research gaps in the field. From previous research, it is evident that load transfer platforms play a pivotal role in controlling deformations and settlements, and geosynthetics contribute significantly to enhancing embankment stability and improving load transfer efficiency. The paper explores various design approaches pertaining to geosynthetic-reinforced and pile-supported (GRPS) embankments, underscoring the historical development and adaptation of these methodologies. Notable techniques encompass Terzaghi's arching theory, the British Standard (BS 8006), the German EBGEO Method, the Dutch standard CUR226, Nordic design, Low et al.'s approach, and a modification proposed by Abusharar et al. Each of these methods presents distinct algorithms for load distribution, arching effectiveness, and geosynthetic reinforcement tension, addressing diverse project requirements and priorities. The paper emphasizes the significance of geosynthetic strain and tension in ensuring the safety and performance of GRPS embankments, advocating for method selection based on project-specific needs and incorporating the latest research findings to enhance design accuracy.
